Cover Crops (340)

Definition & Introduction

Cover Crops as a BMP refers to the use of grasses, legumes or forbs planted to provide seasonal soil cover on cropland when the soil would otherwise be bare. In Minnesota, the cover crop is commonly rye, although oats, barley, alfalfa, buckwheat and hairy vetch are also used. The short growing season in Minnesota limits the use of cover crops although use is expanding as farmers are seeing the environmental and financial benefits of the practice.

The MDA categorizes cover crops into 5 main categories with winter cover crops and catch crops being the most commonly used (MDA, website):

A winter cover crop is planted in late summer or fall to provide soil cover over winter. In Minnesota, winter cover crops

- are commonly planted after potato harvest primarily to reduce wind erosion.
- A catch crop is a cover crop planted after harvesting the main crop, primarily to reduce nutrient leaching. Many southeastern Minnesota growers use cover crops in this way and are cooperating with the Minnesota Department of Agriculture on related research and demonstration projects.
- A smother crop is a cover crop planted primarily to outcompete weeds. In Minnesota, buckwheat and rye cover crops commonly serve this purpose.
- A green manure is a cover crop incorporated into the soil while still green, to improve soil fertility. Currently in Minnesota, green manures are used primarily by organic growers.

- Role in Conservation
- **Definition**
- Link to eFOTG
- Image of practice

 Cover crops can serve as short-rotation forage crops when used for grazing or harvested as immature forage (green chop).

Water Quality & Other Benefits

Water quality benefits of cover crops come from three processes. The first is the literal cover that the crop provides to the soil, reducing erosion from raindrop impact. The second is the potential for the cover crop to take up nutrients that would otherwise be lost from the field through surface or drainage water and the third is increasing soil infiltration.

Minnesota has pioneered cover crop research in northern climates. A 3 year study at Lamberton, MN (Strock et al., 2004) subsurface tile drainage discharge was reduced 11% with a cover crop and that nitrate loss was reduced 13% on a corn-soybean cropping system. These results show a much lower reduction than has been reported around the nation and it has been hypothesized that the reduced effectiveness in Minnesota is due to the short growing season and cold climate (Kaspar, 2008).

An additional study in southwestern Minnesota (Feyereisen et al., 2006) based on modeling concluded that a rye cover crop planted on September 15 and desiccated on May 15 can reduce nitrate losses on average of 6.6 lbs/ac (7.4kg/ha). The other regional example of research is from central lowa where researchers found a nitrate load reduction of 61% for rye cover crop (Kaspar et al., 2007). Jaynes et al. (2004) showed that a cover crop treatment in Minnesota reduced nitrate load by 64% over the control. In a large soil monolith study in lowa, Logsdon et al. (2002) showed rye cover crop and oat cover crop both reduced nitrate leaching and

they recommended late-summer, interseeded small-grain cover crops to reduce nitrate losses from corn-soybean rotations.

Key Design/Implementation Considerations

Cover crops can be used to reduce erosion, hold nutrients and/or provide forage. An excellent factsheet published by the MDA provides a good summary of conditions where farmers are deploying cover crops and can be used as a starting point for designing a cover cropping system (Figure 2). Although this figure shows Winter Rye as the primary cover crop, a large variety of cover crops exist including varieties of grasses, legumes, and brassicas. The Midwest Cover Crop Council has developed a decision tool that can inform planting times and species for specific farms in Minnesota. http://www.mccc.msu.edu/

Cover Crops are often used on beet fields and have become part of the southern MN Beet Growers cooperative P trading program. A precedent-setting program where a co-op provided financial incentives for farmers to use cover crops. http://www.smbsc.com/.

Cost Information

The EQIP payment for cover crops is \$40.00/ac.

Table 10. 2011 EQIP payment schedule (reproduced from MN NRCS 2011)

Component	Unit	PR/unit	HUP/unit	Payment Cap
Legumes or mixed covers on cropland	ac	40	48	\$7,000
Small grain seeding	ac	16	19	\$6,000

- Key Design Information
- Costs

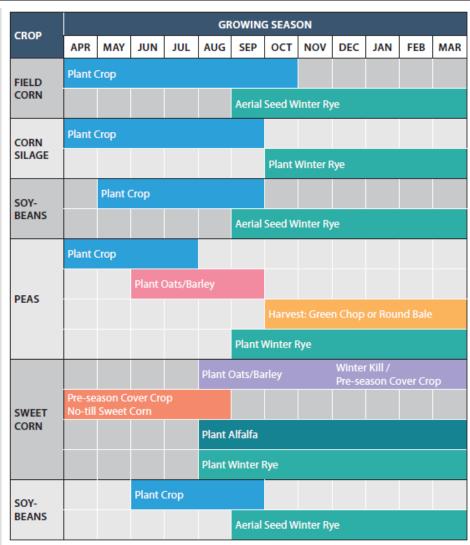

Figure 2. Cover crop uses and timeline by crop type. (adapted from MDA 2005)

Important resources have been reproduced

Operation and Maintenance Considerations

None.

Research Gaps

Although erosion and phosphorus reductions are commonly acknowledged to occur with cover cropped land, there is a lack of research data in Minnesota and the upper Midwest to quantify this reduction.

Appendix B: BMP Effectiveness from National Sources

Other BMP Research from National Sources and Modeling

Many national sources of information regarding effectiveness of agricultural BMPs exist. The following chapter presents research conducted on BMPs outside of Minnesota and the Upper Midwest, selected modeling studies and compilations of BMP effectiveness from national sources. This information may or may not be applicable to Minnesota and Upper Midwest due to climatic, crop and soil differences. This chapter aims to capture much of the important national research and modeling information that didn't fit the criteria for inclusion in the BMP chapters. This chapter follows the same order as the BMP chapters and is separated into avoiding, controlling and trapping.

Avoiding

Conservation Cover

No additional commentary.

Conservation Crop Rotation

The impacts of conservation crop rotation on erosion and phosphorus loss are likely due primarily to the benefit of having the land in perennials for the year. National sources (Merriman, 2009) list the pollutant reduction of sediment and TP as 72% and 60%, respectively, although the relevance of this figure to Minnesota has not been shown.

Table 33. Pollutant reduction estimates in percent for contour buffer strips.

Pollutant	Mean	Minimum	Maximum	Number of Entries	Number of Entries	Source
Total Sediment	78%	30%	94%	20	12	1, 2, 3
Total Phosphorus	62%	49%	80%	11	10	2, 3
Dissolved Phosphorus*	34%	20%	50%	11	9	2, 3
Total Nitrogen	36%	27%	50%	8	8	3
Dissolved Nitrogen	31%	18%	49%	31	8	3
Fecal Coliform	59%	43%	74%	22	2	1

Notes:

This paper describes a good research project using a controlled runoff experiment to estimate pesticide reduction across a buffer strip. It also provides a good summary of previous work on buffer strip pollutant removals. It shows pesticide removals of 46.8%-83.1%.

3 Short Examples of how we thought the handbook would be used.

1. Pollutant Removals

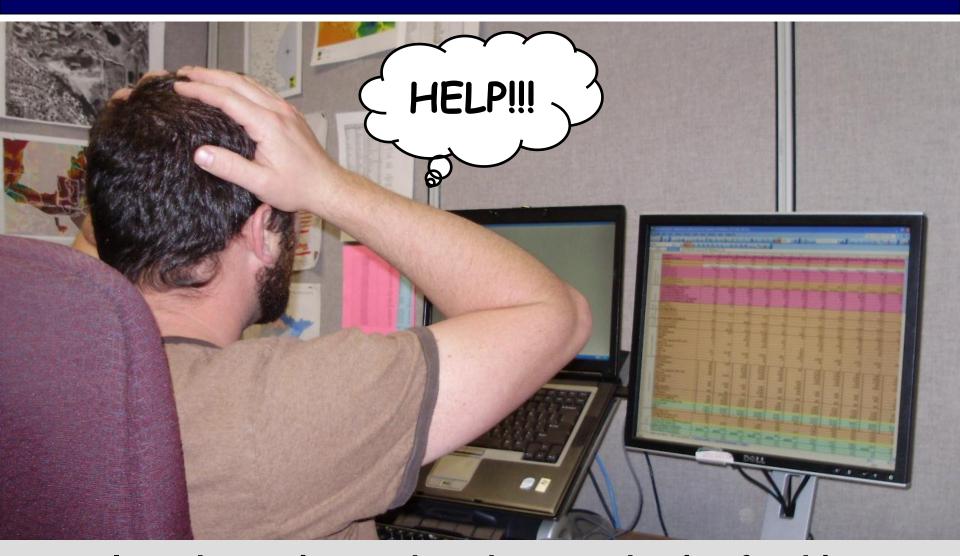

2. Research/Demonstration Projects

3. Implementation Planning - Communication

Example 1 – Pollutant Removals

I need to estimate phosphorus reduction for this Clean Water Fund grant application I'm working on!

Example 1 – Pollutant Removals

Installing Filter Strips

Table 25. Pollutant load reduction estimates in percent for filter strips

Pollutant	Mean	Minimum	Maximum	Number of Entries	Source
Sediment	86	76	91	6	1
Total Phosphorus	65	38	96	4	2,3
Nitrogen	27	27	27	1	3
Atrazine	58	45	71	6	1
Metolachlor	72	68	78	6	1
Cyanazine	69	59	77	6	1

Where do we go from here???

Soil Quality

- 1. Keep soil covered as much as possible.
- 2. Disturb soil as little as possible.
- 3. Keep plants growing throughout the year to feed the soil.
- 4. Diversify as much as possible using crop rotation and cover crops

Minnesota Agricultural Water Quality Certification Program

Under the program, farmers would voluntarily implement and maintain approved conservation plans and receive assurance that their operations meet water quality goals and standards. In return, they would not be required to implement additional water quality practices for the duration of their certification.

Meeting Date	Meeting Location
